Today

Lambda calculus

- ▶ λ -calculus
 - ▶ syntax
 - ▶ reduction rules
- ▶ λ -definable functions
- ▶ primitive recursive functions are λ -definable
- ▶ μ -recursive/partial recursive functions are λ -definable
- ▶ λ -definable functions are Turing computable
- ▶ **Hence: λ -definable = partial recursive = Turing-computable**

Church's Thesis

Alonzo Church (1903 –1995)

Thesis (Church, 1936)

- ▶ *Every total effectively calculable function is recursive.*
- ▶ *Every effectively calculable partial function is partial-recursive.*

λ -terms

Definition

- ▶ **variables:** $x, y, z, x_1, y_1, z_1, \dots \in \Lambda$
- ▶ **λ -abstraction:** x a variable, $M \in \Lambda \implies (\lambda x. M \in \Lambda)$
- ▶ **application:** $M, N \in \Lambda \implies (MN) \in \Lambda$

β -reduction

Definition

- ▶ **One-step β -reduction** \rightarrow_β is defined as the application of the rule:

$$(\lambda x.M)N \rightarrow_\beta M[x := N]$$

in λ -terms $C[(\lambda x.M)N]$ formed by arbitrary λ -term contexts $C[]$, where $(\lambda x.M)N$ is called a **redex**, and furthermore:

$M[x := N]$:= substitution of N for free occurrences of x in M
(using **α -conversion** to avoid variable capture)

- ▶ **Many-step β -reduction** \rightarrow_β^* is defined as the concatenation of zero, one, or more \rightarrow_β -steps.
- ▶ A λ -term M is a **normal form** if it does not contain a redex.

Church numerals

Definition

For every $n \in \mathbb{N}$, the **Church numeral** $\ulcorner n \urcorner$ for n is defined by:

$$\begin{aligned}\ulcorner n \urcorner &:= \lambda f x. f^n x \\ &= \lambda f x. f(\underbrace{f(\dots (f x) \dots)}_n)\end{aligned}$$

Examples.

$$\ulcorner 0 \urcorner = \lambda f x. x$$

$$\ulcorner 1 \urcorner = \lambda f x. f x$$

$$\ulcorner 2 \urcorner = \lambda f x. f(f x)$$

...

Pairs in λ -calculus

Definition

For all $M, N \in \Lambda$ we define the **pair** $\langle M, N \rangle$ consisting of M and N :

$$\langle M, N \rangle := \lambda x. xMN$$

and the **unpairing projections** ρ_1 and ρ_2 :

$$\rho_1 := \lambda p. p(\lambda xy. x)$$

$$\rho_2 := \lambda p. p(\lambda xy. y)$$

Proposition

For all $M_1, M_2 \in \Lambda$ and $i = 1, 2$:

$$\rho_i \langle M_1, M_2 \rangle \rightarrow_{\beta} M_i$$

True, false, if-then-else, **zero?** in λ -calculus

Definition

$$\mathbf{true} := \lambda xy.x$$

$$\mathbf{false} := \lambda xy.y$$

$$\mathbf{if } P \mathbf{ then } Q \mathbf{ else } R := PQR$$

$$\mathbf{zero?} := \lambda x.x(\lambda y.\mathbf{false})\mathbf{true}$$

Proposition

$$\mathbf{if } \mathbf{true} \mathbf{ then } Q \mathbf{ else } R \twoheadrightarrow_{\beta} Q$$

$$\mathbf{if } \mathbf{false} \mathbf{ then } Q \mathbf{ else } R \twoheadrightarrow_{\beta} R$$

$$\mathbf{zero?} \ulcorner 0 \urcorner \twoheadrightarrow_{\beta} \mathbf{true}$$

$$\mathbf{zero?} \ulcorner n + 1 \urcorner \twoheadrightarrow_{\beta} \mathbf{false}$$

λ -definable functions

Definition

- Let $f : \mathbb{N}^n \rightarrow \mathbb{N}$ be total.

A λ -term M_f **represents** f if for all $m_1, \dots, m_n \in \mathbb{N}$:

$$M_f \text{ ' } m_1 \text{ ' } \dots \text{ ' } m_n \text{ ' } \rightarrow_{\beta} \text{ ' } f(m_1, \dots, m_n) \text{ ' }$$

f is **λ -definable** if there exists a λ -term that represents f .

- Let $f : \mathbb{N}^n \rightarrow \mathbb{N}$ be a partial function.

A λ -term M_f **represents** f if for all $m_1, \dots, m_n \in \mathbb{N}$:

$$f(m_1, \dots, m_n) \downarrow \implies M_f \text{ ' } m_1 \text{ ' } \dots \text{ ' } m_n \text{ ' } \rightarrow_{\beta} \text{ ' } f(m_1, \dots, m_n) \text{ ' }$$

$$f(m_1, \dots, m_n) \uparrow \implies M_f \text{ ' } m_1 \text{ ' } \dots \text{ ' } m_n \text{ ' } \text{ has no normal form}$$

f is **λ -definable** if there exists a λ -term that represents f .

λ -definable

Examples.

- ▶ **successor:** $M_{\text{succ}} := \lambda n f x. f(n f x)$
- ▶ **addition:** $M_+ := \lambda m n f x. m f(n f x)$
- ▶ **multiplication:** $M_{\times} := \lambda m n f x. m(n f)x$
- ▶ **exponentiation:** $M_E := \lambda m n f x. m n f x$
- ▶ **unary constant zero function:** $M_{C_0^1} = \lambda m. \ulcorner 0 \urcorner$
- ▶ **projection function:** $M_{\pi_i^k} = \lambda n_1 \dots n_k. n_i$

Typical features of 'computationally complete' MoC's

- ▶ storage (unbounded)
- ▶ control (finite, given)
- ▶ modification
 - ▶ of (immediately accessible) stored data
 - ▶ of control state
- ▶ conditionals
- ▶ loop
- ▶ stopping condition

The Book

([1]) **Henk**drik Pieter (Henk) Barendregt

Exercises

- ▶ Reduce $(\lambda xy.x)(\lambda x.xx)(\lambda x.xx)$ to normal form.
- ▶ Find two distinct λ -terms representing the successor function on Church-numerals (hint: think of $n + 1$ and $1 + n$). Prove that your λ -terms are not- β -equivalent.
- ▶ Try computing the normal form of the Y -combinator, i.e. of AA where $A = \lambda am.m(aam)$, e.g. by each time selecting the leftmost redex (reducible expression, i.e. subexpression of the shape $(\lambda x.M)N$).

Primitive recursive functions are λ -definable

Proposition

Every primitive recursive function is λ -definable.

Proof (The case of primitive recursion).

Let $h := \text{pr}(f; g) : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ for prim.rec. $f : \mathbb{N}^n \rightarrow \mathbb{N}$, $g : \mathbb{N}^{n+2} \rightarrow \mathbb{N}$:

$$h(\vec{x}, 0) = f(\vec{x})$$

$$h(\vec{x}, y + 1) = g(\vec{x}, h(\vec{x}, y), y)$$

Suppose that f and g are represented by $M_f, M_g \in \Lambda$, respectively.

$$\text{Init} := \langle \ulcorner 0 \urcorner, M_f x_1 \dots x_n \rangle$$

$$\text{Step} := \lambda p. \langle M_{\text{succ}}(\rho_1 p), M_g x_1 \dots x_n (\rho_2 p) (\rho_1 p) \rangle$$

Then the following λ -term M_h represents h :

$$M_h := \lambda x_1 \dots x_n x. \rho_2 (x \text{ Step Init})$$

Primitive recursive functions ($\mathbb{N}^n \cup \mathbb{N}^0 \rightarrow \mathbb{N}$)

Base functions:

- ▶ $\mathcal{O} : \mathbb{N}^0 = \{\emptyset\} \rightarrow \mathbb{N}$, $\emptyset \mapsto 0$ (0-ary constant-0 function)
- ▶ $\text{succ} : \mathbb{N} \rightarrow \mathbb{N}$, $x \mapsto x + 1$ (successor function)
- ▶ $\pi_i^n : \mathbb{N}^n \rightarrow \mathbb{N}$, $\vec{x} = \langle x_1, \dots, x_n \rangle \mapsto x_i$ (projection function)

Closed under operations:

- ▶ **composition**: if $f : \mathbb{N}^k \rightarrow \mathbb{N}$, and $g_i : \mathbb{N}^n \rightarrow \mathbb{N}$ are prim. rec., then so is $h = f \circ (g_1 \times \dots \times g_k) : \mathbb{N}^n \rightarrow \mathbb{N}$:

$$h(\vec{x}) = f(g_1(\vec{x}), \dots, g_k(\vec{x}))$$
- ▶ **primitive recursion**: if $f : \mathbb{N}^n \rightarrow \mathbb{N}$, $g : \mathbb{N}^{n+2} \rightarrow \mathbb{N}$ are prim. rec., then so is $h = \text{pr}(f; g) : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$:

$$h(\vec{x}, 0) = f(\vec{x})$$

$$h(\vec{x}, y + 1) = g(\vec{x}, h(\vec{x}, y), y)$$

μ -recursion, and partial recursive functions

Definition

A partial function $f : \mathbb{N}^n \rightarrow \mathbb{N}$ is called **partial recursive** if it can be specified from **base functions** (\mathcal{O} , **succ**, π_i^n) by successive applications of **composition**, **primitive recursion**, and **unbounded minimisation**.

A partial recursive function is called **(total) recursive** if it is total.

Let $f : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ **total**. Then the partial function defined by:

$$\mu(f) : \mathbb{N}^n \rightarrow \mathbb{N}$$

$$\vec{x} \mapsto \begin{cases} \min(\{y \mid f(\vec{x}, y) = 0\}) & \dots \exists y (f(\vec{x}, y) = 0) \\ \uparrow & \dots \text{else} \end{cases}$$

is called the **unbounded minimisation of f** .

Reminder: Kleene's normal form theorem

Theorem

For every *partial recursive* function $h : \mathbb{N}^n \rightarrow \mathbb{N}$ there exist *primitive recursive* functions $f : \mathbb{N} \rightarrow \mathbb{N}$ and $g : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ such that:

$$h(x_1, \dots, x_n) = (f \circ \mu(g))(x_1, \dots, x_n)$$

μ -recursive/partial recursive \Rightarrow λ -definable

Theorem

Every μ -recursive/partial recursive function is λ -definable.

Proof.

Let $h : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ be partial recursive.

Then by Kleene's normal form theorem there exist $g : \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ and $f : \mathbb{N} \rightarrow \mathbb{N}$ such that:

$$h(\vec{x}) = f \circ \mu(g)(\vec{x}) = f(\mu z. [g(\vec{x}, z) = 0])$$

Let M_f and M_g be λ -terms representing f and g , respectively. Let:

$$W := \lambda y. \text{if } (\text{zero? } M_g x_1 \dots x_n y) \text{ then } (\lambda w. M_f y) \text{ else } (\lambda w. w(M_{\text{succ}} y)w)$$

Then the following λ -term M_h represents h :

$$M_h := \lambda x_1 \dots x_n. W \text{ '0' } W$$

A normalizing reduction strategy

Normal order reduction strategy \xrightarrow{n} :

only perform \rightarrow_β -steps in left-most positions.

Theorem

The *normal order reduction strategy* in is normalizing in λ -calculus, that is:

$$M \twoheadrightarrow_\beta N \wedge N \text{ is a normal form} \implies M \xrightarrow{n} N$$

λ -definable \Rightarrow Turing-computable

Theorem

Every λ -definable function is Turing computable.

Idea of the Proof.

Let $f : \mathbb{N}^n \rightarrow \mathbb{N}$ be a partial function that is λ -definable. Then there exists a λ -term M_f that represents f .

To compute f , one can build a Turing machine M that, for given $m_1, \dots, m_n \in \mathbb{N}$:

- ▶ simulates a normal order rewrite sequence on $M_f \ulcorner m_1 \urcorner \dots \ulcorner m_n \urcorner$ to obtain the normal form $\ulcorner f(m_1, \dots, m_n) \urcorner$ □

Summary

Lambda calculus

- ▶ λ -calculus
 - ▶ syntax
 - ▶ reduction rules
- ▶ λ -definable functions
- ▶ primitive recursive functions are λ -definable
- ▶ μ -recursive/partial recursive functions are λ -definable
- ▶ λ -definable functions are Turing computable
- ▶ Hence: λ -definable = partial recursive = Turing-computable
